May 20, 2020

gs-rs is a Rust framework for the optimization of non-linear least squares problems embeddable as a (hyper)graph. It is suitable for the optimization of an error function with respect to a set of parameters as in SLAM (simultaneous localization and mapping) or BA (bundle adjustment).

1 Optimization Algorithm

1.1 Background Literature

The optimization algorithm used by **gs-rs** is based on that which parts of **g2o** uses. This paper should suffice to understand the optimization's implementation in **gs-rs**. The following papers by the developers of **g2o** are recommended if a deeper understanding of the theory behind the algorithm is of interest:

- *g2o: A General Framework for Graph Optimization*, Kümmerle et al. [1]: This paper documents the derivation of the algorithm's structure.
- *A Tutorial on Graph-Based SLAM*, Grisetti et al. [2]: This paper contains additional comments on the calculations in 2D and 3D. Here it is presented how the least squares optimization works on a manifold.

1.2 Iteration Steps

Given a specific number of iterations n and the initial guess $x_i^{(0)}$ for each variable, the optimizer algorithm will repeat the following steps n times:

1. Calculate H and b by setting them to $\mathbf{0}$, then looping through all factors and updating their non-fixed variables' entries in H and b .
2. Calculate Δx , the vector containing data about how much each current variable guess $x_i^{(k)}$ should be updated in this step, by solving the linear system

$$H\Delta x = -b^T. \quad (1)$$

3. Update the guesses for each non-fixed variable x_i with

$$x_i^{(k+1)} = x_i^{(k)} + \Delta x_i. \quad (2)$$

In the case of 2D variables with a rotation, normalize it to $[-\pi, \pi)$.

How the parts of H and b are calculated depends on the exact factor type. In the following sections, the calculation is described for all 2D and 3D factors supported by **gs-rs**.

2 Optimization in 2D

In all cases the factor's increments on parts of H and b , H^{fac} and b^{fac} respectively, will be computed as follows:

$$H^{fac} = J^T * \Omega * J, \quad (3)$$

$$b^{fac} = e^T * \Omega * J, \quad (4)$$

where Ω , J and e are the factor's information matrix, Jacobian matrix and error vector, respectively. While Ω is a given constant of the factor, J and e have to be calculated for each factor in each iteration.

If the factor only involves the variable x_i , H and b are updated as follows:

$$H_{ii} = H_{ii} + H^{fac}, \quad (5)$$

$$b_i = b_i + b^{fac}, \quad (6)$$

where the subscripts of H and b denote the row and column index of the submatrix or subvector assigned to the respective variable. If the factor involves two variables x_i and x_j , H^{fac} and b^{fac} will have the structure

$$H^{fac} = \begin{pmatrix} H_{ii}^{fac} & H_{ij}^{fac} \\ H_{ji}^{fac} & H_{jj}^{fac} \end{pmatrix} \quad (7)$$

and

$$b^{fac} = \begin{pmatrix} b_i^{fac} & b_j^{fac} \end{pmatrix}, \quad (8)$$

respectively, such that H_{mn} will be incremented by H_{mn}^{fac} and b_n will be incremented by b_n^{fac} , analogously to equations (5) and (6). Fixed variables are excluded from H and b and therefore do not have any submatrices or subvectors which would need to be updated. In this case, these parts of H^{fac} and b^{fac} are simply ignored.

In the following sections, the individual 2D factors' calculations of J and e are presented. The functions $pos(x)$ and $rot(x)$ will be used to refer to the 2D position vector and the rotation angle of a 2D pose x , respectively. Similarly, the functions $pos_x(x)$ and $pos_y(x)$ will be used to refer to the single value within the respective dimension.

Furthermore, the rotation matrices are denoted such that

$$R_\alpha = \begin{pmatrix} \cos(\alpha) & -\sin(\alpha) \\ \sin(\alpha) & \cos(\alpha) \end{pmatrix} \quad (9)$$

equals the rotation matrix with the angle α in 2D, and

$$R_z(\alpha) = \begin{pmatrix} \cos(\alpha) & -\sin(\alpha) & 0 \\ \sin(\alpha) & \cos(\alpha) & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad (10)$$

equals the rotation matrix with the angle α in 3D.

2.1 Position2D

The *Position2D* factor involves one *VehicleVariable* x_v . The Jacobian matrix J in this case is

$$J = R_z(-rot(x_v)). \quad (11)$$

Given the measurement x_m , the error vector

$$e = R_{-rot(x_m)} * (pos(x_v) - pos(x_m)) \quad (12)$$

can be computed as well.

2.2 Odometry2D

The *Position2D* factor involves two *VehicleVariables* x_i and x_j . Given the measurement x_{ij} , the Jacobian matrix J is calculated as follows:

$$\Delta x_{ij} = x_j - x_i \quad (13)$$

$$\sin_i = \sin(\text{rot}(x_i)) \quad (14)$$

$$\cos_i = \cos(\text{rot}(x_i)) \quad (15)$$

$$J_i = R_z(-\text{rot}(x_{ij})) * \begin{pmatrix} -\cos_i & -\sin_i & -\sin_i * \text{pos}_x(\Delta x_{ij}) + \cos_i * \text{pos}_y(\Delta x_{ij}) \\ \sin_i & -\cos_i & -\cos_i * \text{pos}_x(\Delta x_{ij}) - \sin_i * \text{pos}_y(\Delta x_{ij}) \\ 0 & 0 & -1 \end{pmatrix} \quad (16)$$

$$J_j = R_z(-\text{rot}(x_{ij})) * R_z(-\text{rot}(x_i)) \quad (17)$$

$$J = \begin{pmatrix} J_i & J_j \end{pmatrix} \quad (18)$$

The error vector e is computed as follows:

$$e_{pos} = R_{-\text{rot}(x_{ij})} * (R_{-\text{rot}(x_i)} * \text{pos}(\Delta x_{ij}) - \text{pos}(x_{ij})) \quad (19)$$

$$e_{rot} = \text{rot}(\Delta x_{ij}) - \text{rot}(x_{ij}) \quad (20)$$

After normalizing e_{rot} to $[-\pi, \pi)$ with $\text{norm}(e_{rot})$ the full error vector can be constructed with

$$e = \begin{pmatrix} e_{pos} \\ \text{norm}(e_{rot}) \end{pmatrix}. \quad (21)$$

2.3 Observation2D

The *Position2D* factor involves one *VehicleVariable* x_i and one *LandmarkVariable* x_j . The measurement is denoted as x_{ij} , analogously to the previous section. Although x_j and x_{ij} are only positions rather than poses and therefore do not contain a rotation angle, the functions $\text{pos}(x)$, $\text{pos}_x(x)$ and $\text{pos}_y(x)$ will be used nevertheless to make the calculation path more understandable. Given the measurement x_{ij} , the Jacobian matrix J is calculated as follows:

$$\text{pos}(\Delta x_{ij}) = \text{pos}(x_j) - \text{pos}(x_i) \quad (22)$$

$$\sin_i = \sin(\text{rot}(x_i)) \quad (23)$$

$$\cos_i = \cos(\text{rot}(x_i)) \quad (24)$$

$$J_i = \begin{pmatrix} -\cos_i & -\sin_i & -\sin_i * \text{pos}_x(\Delta x_{ij}) + \cos_i * \text{pos}_y(\Delta x_{ij}) \\ \sin_i & -\cos_i & -\cos_i * \text{pos}_x(\Delta x_{ij}) - \sin_i * \text{pos}_y(\Delta x_{ij}) \end{pmatrix} \quad (25)$$

$$J_j = R_{-\text{rot}(x_i)} \quad (26)$$

$$J = \begin{pmatrix} J_i & J_j \end{pmatrix} \quad (27)$$

The error vector e is computed as follows:

$$e = R_{-\text{rot}(x_i)} * \text{pos}(\Delta x_{ij}) - \text{pos}(x_{ij}) \quad (28)$$

3 Optimization in 3D

3D optimization is not supported yet. In the future, the following factors should be able to contribute to the optimization:

3.1 Position3D

3.2 Odometry3D

3.3 Observation3D
